# Low Standby-Power Quasi-Resonant Primary-Side Converter

### **General Description**

The PN8386 consists of a Low Standby-Power Quasi-Resonant (QR) Primary-Side controller and a 650V avalanche-rugged smart power VDMOSFET, specifically designed for a high performance AC/DC charger or adaptor with minimal external components. PN8386 operates in primary-side sensing and regulation, so opto-coupler and TL431 could be eliminated. Because of internal HV Start-up circuit, the system with PN8386 can achieve less than 50mW standby power consumption (264VAC). In CV mode, multi-mode and quasi resonant technique is utilized to achieve high efficiency, avoid audible noise and make the system meeting Energy star class VI. Good load regulation is achieved by the built-in cable drop compensation. In CC mode, the current and output power setting can be adjusted externally by the sense resistor at CS pin. PN8386 offers complete protections including Cycle-by-Cycle current limiting protection (OCP), over voltage protection (OVP), over temperature protection (OTP) and CS open or short protection (CSO/SP) etc.

#### Applications

- Switch AC/DC Adaptor
- Battery Charger

#### Features

- Internal 650 V avalanche-rugged smart power VDMOSFET
- Internal HV Start-up Circuit, Standby power consumption
  < 50mW at 264VAC</li>
- Multi-mode and Quasi-Resonant technique
- ±5% CC Regulation at Universal AC input
- Primary-side Sensing and Regulation without TL431 and Opto-coupler
- Programmable Cable Drop Compensation
- No-need Control Loop Compensation Capacitance
- Excellent Protection Coverage:
  - ♦ Over Temperature Protection (OTP)
  - ♦ VDD Under/Over Voltage Protection(UVLO&OVP)
  - ♦ Cycle-by-Cycle Current Limiting (OCP)
  - ♦ Cs Short/Open Protection (CS O/SP)

# **Typical Characteristics Plots**

#### **Functional Description**

The PN8386 is a high performance CC/CV primary-side controller. PN8386 operates in primary-side sensing and regulation, so opto-coupler and TL431 could be eliminated. Proprietary built-in CV and CC control can achieve high precision CC/CV control meeting most charger and adaptor application requirements. Internal HV Start-up circuit and the chip's low consumption help the system to meet strict standby power standard.

#### 1. HV Start up Control

At start up, the internal high-voltage start-up circuit provides the internal bias and charges the external VDD capacitor, so that PN8386 starts up quickly. When VDD reaches  $V_{DDon}$ , the device starts switching and the internal high-voltage current source stops charging the capacitor. The device keeps in normal operation provided as long as VDD keeps above  $V_{DDoff}$ . After startup, the bias is supplied from the auxiliary transformer winding, the current of HV start-up circuit is designed to be very low so that the power consumption is very low.

#### 2. CC Operation Mode

In CC operation mode, the PN8386 captures the auxiliary flyback signal at FB pin through a resistor dividing-network. The pulse width of the auxiliary flyback signal determines the PN8386 oscillator frequency. The higher the output voltage is, the shorter the pulse width is, and the higher the chip oscillator frequency is, thus the constant output current can be achieved.

The current waveform of DCM mode is shown in Figure 1. During MOSFET turn-on time, the current in the primary winding (Ipri) ramps up. When MOSFET turns off, the energy stored in the primary winding is transferred to the secondary side, so the peak current in the secondary winding is

$$I_{\text{sec}_{pk}} = I_{pri_{pk}} \times N_{ps} \tag{1}$$

The output current is

$$I_{O} = \frac{I_{\text{sec}\_pk}}{2} \times \frac{T_{demag}}{T_{P}} = \frac{1}{2} N_{PS} \frac{V_{CS}}{R_{sense}} \frac{T_{demag}}{T_{P}} \quad (2)$$

Because Vipk is constant and Tp is equal to tow times Tdemag, the output current Io is constant.

Figure 1. The current waveform of DCM mode

#### 3. CV Operation Mode

In CV mode, PN8386 uses a pulse to sample  $V_{FB}$  and it is hold until the next sampling. The sampled voltage is compared with  $V_{REF_{CV}}$  and the error is amplified. The error amplified output reflects the load condition and controls the switching off time to regulate the output voltage, thus constant output voltage can be achieved.

The relationship between the output voltage and  $V_{\text{REF CV}}$  is

$$Vo = (V_{REF_{CV}} \times \frac{R1 + R2}{R2}) \times \frac{N_s}{N_{AUX}}$$
(3)

 $N_s$  means Secondary winding,  $N_{AUX}$ 

means Auxiliary winding

The PN8386 operates in PFM\_QR mode during full load mode, since the peak current (Ipeak) of MOSFET is constant, the chip frequency decreases while the output current decreases. When the switching frequency approaches to 25kHz, the PN8386 enters PWM\_QR mode, the chip frequency decreases slowly while the output current decreases, the Ipeak decreases while the output current decreases. Therefore the PN8386 can avoid audible noise, while achieving high efficiency at 25% load conditions. When Vcs decreases to 170mV, the PN8386 enters Standby mode. In this mode, Ipeak

# PN8386

keeps around constant, the chip oscillator frequency decreases while the output current decreases. Figure 2 illustrates the relations of the switching frequency, Ipeak and Loading for PN8386.

Figure 2. The Switching Frequency, Vipeak VS. LOAD

# 4. Current Sensing and Leading Edge Blanking

Cycle-by-Cycle current limiting is offered in PN8386. The switch current is detected by a sense resistor at CS pin. The CC set-point and maximum output power can be externally adjusted by external current sense resistor at CS pin. An internal leading edge blanking circuit chops off the sensed voltage spike at initial power MOSFET on-state so that the external RC filtering on sense input is no longer needed.

#### 5. Programmable Cable Drop Compensation

In PN8386, an offset voltage is generated at FB pin by an internal current flowing into the divider resister, as shown in Figure 3. The Cable Drop Compensation block compensates the voltage drop across the cable. As the load current decreases from full load to no load, the voltage drop across the cable decreases. It can be programmed by adjusting the external resistor R2 or R1 at FB pin. The maximum compensation is

$$\frac{V_{cable}}{V_O} = \frac{I_{cable} \times (R2 / / R1)}{2.5V}$$
(4)

Because of the influence of the chip's sampling position and devices of the system, the actual

maximum compensation is less than theoretical value.

Figure 3. Icable

# 6. Reference Negative Temperature Compensation

As shown in Figure 3, the voltage of FB pin is

$$V_{FB} = K(V_o + \Delta V), K = \frac{R2 \times N_{AUX}}{(R1 + R2) \times N_s} \quad (5)$$

Where  $\Delta V$  has a negative temperature coefficient, K is a constant.

In PN8386, the voltage reference uses the negative temperature compensation technology. At room temperature, the voltage reference is 2.5V. The voltage reference ( $V_{REF_CV}$ ) decreases while the temperature of chip increases. The reference negative temperature compensation block compensates the  $\Delta V$ , thus the output voltage keeps constant at full range of temperature. The reference negative temperature compensation improves output precision.

#### 7. Quasi-Resonant Switching

The PN8386 incorporates a unique proprietary quasi-resonant switching scheme that achieves valley-mode turn on for every switching cycle in CV mode. This unique feature greatly reduces the switching loss. The actual switching frequency can vary slightly cycle by cycle, providing the additional benefit of reducing EMI.

Figure 4. QR Mode

#### 8. Protection Control

The PN8386 has several self-protection functions, such as Cycle-by-Cycle current limiting (OCP), Over-Voltage Protection, Over-Temperature Protection, Feedback Loop open Protection, Output short circuit Protection, CS resistor open/short circuit Protection and Under Voltage Lockout on VDD. All protections are self-recovered.

# **Typical Application**

#### **Component Parameter and Layout Considerations:**

1. VDD capacitor EC1 should be placed at the nearest place from the VDD pin and the GND pin.
